

Python Dictionaries

Chapter 9

Python for Everybody
www.py4e.com

What is a Collection?

- A collection is nice because we can put more than one value in it and carry them all around in one convenient package
- We have a bunch of values in a single “variable”
- We do this by having more than one place “in” the variable
- We have ways of finding the different places in the variable

What is Not a “Collection”?

Most of our **variables** have one value in them - when we put a new value in the **variable** - the old value is overwritten

```
$ python
>>> x = 2
>>> x = 4
>>> print(x)
4
```

A Story of Two Collections..

- List

- A linear collection of values that stay in order

- Dictionary

- A “bag” of values, each with its own label

Dictionaries

http://en.wikipedia.org/wiki/Associative_array

Dictionaries

- Dictionaries are Python's most powerful data collection
- Dictionaries allow us to do fast database-like operations in Python
- Dictionaries have different names in different languages
 - Associative Arrays - Perl / PHP
 - Properties or Map or HashMap - Java
 - Property Bag - C# / .Net

Dictionaries

- Lists **index** their entries based on the position in the list
- **Dictionaries** are like bags - no order
- So we **index** the things we put in the **dictionary** with a “lookup tag”

```
>>> purse = dict()
>>> purse['money'] = 12
>>> purse['candy'] = 3
>>> purse['tissues'] = 75
>>> print(purse)
{'money': 12, 'tissues': 75, 'candy': 3}
>>> print(purse['candy'])
3
>>> purse['candy'] = purse['candy'] + 2
>>> print(purse)
{'money': 12, 'tissues': 75, 'candy': 5}
```

Comparing Lists and Dictionaries

Dictionaries are like **lists** except that they use **keys** instead of numbers to look up **values**

```
>>> lst = list()
>>> lst.append(21)
>>> lst.append(183)
>>> print(lst)
[21, 183]
>>> lst[0] = 23
>>> print(lst)
[23, 183]
```

```
>>> ddd = dict()
>>> ddd['age'] = 21
>>> ddd['course'] = 182
>>> print(ddd)
{'course': 182, 'age': 21}
>>> ddd['age'] = 23
>>> print(ddd)
{'course': 182, 'age': 23}
```

```
>>> lst = list()
>>> lst.append(21)
>>> lst.append(183)
>>> print(lst)
[21, 183]
>>> lst[0] = 23
>>> print(lst)
[23, 183]
```

List

Key	Value
[0]	21
[1]	183

lst

```
>>> ddd = dict()
>>> ddd['age'] = 21
>>> ddd['course'] = 182
>>> print(ddd)
{'course': 182, 'age': 21}
>>> ddd['age'] = 23
>>> print(ddd)
{'course': 182, 'age': 23}
```

Dictionary

Key	Value
['course']	182
['age']	21

ddd

Dictionary Literals (Constants)

- Dictionary literals use curly braces and have a list of **key** : **value** pairs
- You can make an **empty dictionary** using empty curly braces

```
>>> jjj = { 'chuck' : 1 , 'fred' : 42, 'jan': 100}
>>> print(jjj)
{'jan': 100, 'chuck': 1, 'fred': 42}
>>> ooo = { }
>>> print(ooo)
{}
>>>
```

Most Common Name?

Most Common Name?

marquard	cwen	cwen
zhen	marquard	zhen
csev	zhen	csev
zhen	csev	marquard
		zhen

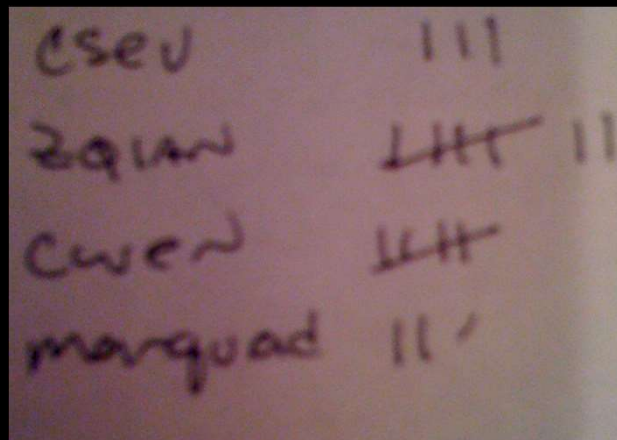

Most Common Name?

marquard

cwen

cwen

zhen

zhen

csev

csev

zhen

csev

marquard

zhen

Many Counters with a Dictionary

One common use of dictionaries is **counting** how often we “see” something

```
>>> ccc = dict()
>>> ccc['csev'] = 1
>>> ccc['cwen'] = 1
>>> print(ccc)
{'csev': 1, 'cwen': 1}
>>> ccc['cwen'] = ccc['cwen'] + 1
>>> print(ccc)
{'csev': 1, 'cwen': 2}
```

Key

Value

csev	111
cwen	11
marquard	11

Dictionary Tracebacks

- It is an **error** to reference a key which is not in the dictionary
- We can use the **in** operator to see if a key is in the dictionary

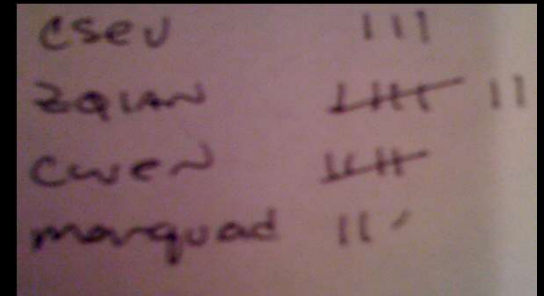

```
>>> ccc = dict()
>>> print(ccc['csev'])
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
KeyError: 'csev'
>>> 'csev' in ccc
False
```

When We See a New Name

When we encounter a new name, we need to add a new entry in the **dictionary** and if this the second or later time we have seen the **name**, we simply add one to the count in the **dictionary** under that **name**

```
counts = dict()
names = ['csev', 'cwen', 'csev', 'zqian', 'cwen']
for name in names:
    if name not in counts:
        counts[name] = 1
    else:
        counts[name] = counts[name] + 1
print(counts)
```

{'csev': 2, 'zqian': 1, 'cwen': 2}

The `get` Method for Dictionaries

The pattern of checking to see if a `key` is already in a dictionary and assuming a default value if the `key` is not there is so common that there is a `method` called `get()` that does this for us

Default value if key does not exist
(and no Traceback).

```
if name in counts:  
    x = counts[name]  
else :  
    x = 0
```

```
x = counts.get(name, 0)
```

```
{'csev': 2, 'zqian': 1, 'cwen': 2}
```

Simplified Counting with `get()`

We can use `get()` and provide a **default value of zero** when the **key** is not yet in the dictionary - and then just add one

```
counts = dict()
names = ['csev', 'cwen', 'csev', 'zqian', 'cwen']
for name in names :
    counts[name] = counts.get(name, 0) + 1
print(counts)
```

Default

`{'csev': 2, 'zqian': 1, 'cwen': 2}`

Simplified Counting with `get()`

```
counts = dict()
names = ['csev', 'cwen', 'csev', 'zqian', 'cwen']
for name in names:
    counts[name] = counts.get(name, 0) + 1
print(counts)
```

Counting Words in Text

Writing programs (or programming) is a very creative and rewarding activity. You can write programs for many reasons ranging from making your living to solving a difficult data analysis problem to having fun to helping someone else solve a problem. This book assumes that everyone needs to know how to program and that once you know how to program, you will figure out what you want to do with your newfound skills.

We are surrounded in our daily lives with computers ranging from laptops to cell phones. We can think of these computers as our “personal assistants” who can take care of many things on our behalf. The hardware in our current-day computers is essentially built to continuously ask us the question, “What would you like me to do next?”

Our computers are fast and have vast amounts of memory and could be very helpful to us if we only knew the language to speak to explain to the computer what we would like it to do next. If we knew this language we could tell the computer to do tasks on our behalf that were repetitive. Interestingly, the kinds of things computers can do best are often the kinds of things that we humans find boring and mind-numbing.

Counting Pattern

```
counts = dict()
print('Enter a line of text:')
line = input('')

words = line.split()

print('Words:', words)

print('Counting...')
for word in words:
    counts[word] = counts.get(word, 0) + 1
print('Counts', counts)
```

The general pattern to count the words in a line of text is to **split** the line into words, then loop through the words and use a **dictionary** to track the count of each word independently.

```
python wordcount.py
```

```
Enter a line of text:
```

```
the clown ran after the car and the car ran into the tent  
and the tent fell down on the clown and the car
```

```
Words: ['the', 'clown', 'ran', 'after', 'the', 'car',  
'and', 'the', 'car', 'ran', 'into', 'the', 'tent', 'and',  
'the', 'tent', 'fell', 'down', 'on', 'the', 'clown',  
'and', 'the', 'car']
```

```
Counting...
```

```
Counts {'and': 3, 'on': 1, 'ran': 2, 'car': 3, 'into': 1,  
'after': 1, 'clown': 2, 'down': 1, 'fell': 1, 'the': 7,  
'tent': 2}
```

<http://www.flickr.com/photos/71502646@N00/2526007974/>

```
counts = dict()
line = input('Enter a line of text:')
words = line.split()

print('Words:', words)
print('Counting...')

for word in words:
    counts[word] = counts.get(word,0) + 1
print('Counts', counts)
```

```
python wordcount.py
```

Enter a line of text:

the clown ran after the car and the car ran
into the tent and the tent fell down on the
clown and the car

Words: ['the', 'clown', 'ran', 'after', 'the', 'car',
'and', 'the', 'car', 'ran', 'into', 'the', 'tent', 'and',
'the', 'tent', 'fell', 'down', 'on', 'the', 'clown',
'and', 'the', 'car']

Counting...

Counts {'and': 3, 'on': 1, 'ran': 2, 'car': 3,
'into': 1, 'after': 1, 'clown': 2, 'down': 1, 'fell':
1, 'the': 7, 'tent': 2}

Definite Loops and Dictionaries

Even though **dictionaries** are not stored in order, we can write a **for** loop that goes through all the **entries** in a **dictionary** - actually it goes through all of the **keys** in the **dictionary** and **looks up** the values

```
>>> counts = { 'chuck' : 1 , 'fred' : 42, 'jan': 100}
>>> for key in counts:
...     print(key, counts[key])
...
jan 100
chuck 1
fred 42
>>>
```

Retrieving Lists of Keys and Values

You can get a list of **keys**, **values**, or **items (both)** from a dictionary

```
>>> jjj = { 'chuck' : 1 , 'fred' : 42, 'jan': 100}
>>> print(list(jjj))
['jan', 'chuck', 'fred']
>>> print(jjj.keys())
['jan', 'chuck', 'fred']
>>> print(jjj.values())
[100, 1, 42]
>>> print(jjj.items())
[('jan', 100), ('chuck', 1), ('fred', 42)]
>>>
```

What is a “tuple”? - coming soon...

Bonus: Two Iteration Variables!

- We loop through the **key-value** pairs in a dictionary using ***two*** iteration variables

```
jjj = { 'chuck' : 1 , 'fred' : 42, 'jan': 100}  
for aaa,bbb in jjj.items() :  
    print(aaa, bbb)
```

- Each iteration, the first variable is the **key** and the second variable is the corresponding **value** for the key

```
jan 100  
chuck 1  
fred 42
```

aaa	bbb
[jan]	100
[chuck]	1
[fred]	42

```
name = input('Enter file:')
handle = open(name)

counts = dict()
for line in handle:
    words = line.split()
    for word in words:
        counts[word] = counts.get(word,0) + 1

bigcount = None
bigword = None
for word,count in counts.items():
    if bigcount is None or count > bigcount:
        bigword = word
        bigcount = count

print(bigword, bigcount)
```

```
python words.py
Enter file: words.txt
to 16
```

```
python words.py
Enter file: clown.txt
the 7
```

Using two nested loops

Summary

- What is a collection?
- Lists versus Dictionaries
- Dictionary constants
- The most common word
- Using the `get()` method
- Hashing, and lack of order
- Writing dictionary loops
- Sneak peek: tuples
- Sorting dictionaries
